NGP-054 — CANARY WEBHOOK HONEYPOT

ABSTRACT:

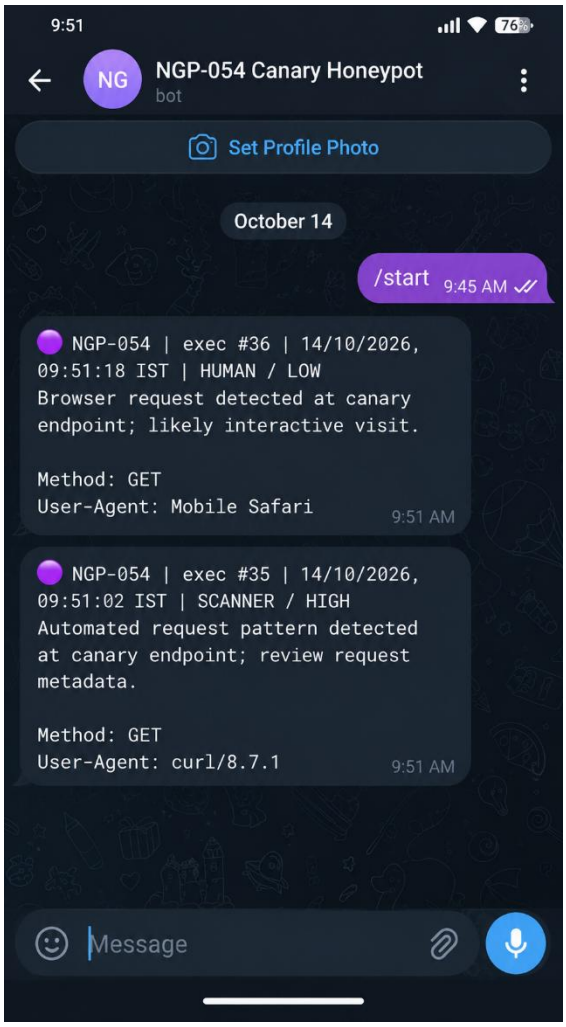

The NGP-054 Canary Webhook Honeypot is a cybersecurity project designed to monitor suspicious activity by using a specially created webhook endpoint as a digital trap. A webhook is a URL that can receive HTTP requests from browsers, scripts, bots, and automated security scanners. When someone accesses the monitored endpoint, the system captures important request details, including the source IP address, User-Agent, HTTP headers, request method, and timestamp. These details are passed to an Artificial Intelligence (AI) classification system, which analyzes the request and classifies the visitor as a human, bot, or scanner. The system also assigns a severity level of LOW, MEDIUM, or HIGH and generates a short explanation of the detected activity. To improve reliability, the AI response is validated before an alert is sent. If the response is invalid, the system retries the classification once and sends a fallback alert if validation fails again. Using n8n workflow automation and Telegram integration, the system delivers security alerts containing the execution ID, timestamp, classification, severity, and summary. The system can be tested using a mobile browser and the curl command-line tool to compare different request patterns. This project demonstrates how deception-based monitoring, AI-assisted analysis, and automated alerting can support faster identification and initial analysis of potentially suspicious web activity.
